

Distributed Programming University Project

H.D.S

1st January 2024

Student: Angelo Rosa

The project

Brief

H.D.S (Hashcat-Distributed-Service) is a university project written entirely in **Go**, designed to distribute WPA handshake cracking tasks across multiple **Hashcat** clients. It serves as a practical proof of concept for distributed password-cracking workloads.

Run the Application (in Test Mode) with Docker

Since `client` within docker runs a GUI application using **Raylib**, it requires access to the host's desktop environment. A utility called `xhost` is needed (`xorg-xhost` on Arch Linux).

Run the following commands:

```
export DISPLAY=:0.0 && \  
xhost +local:docker && \  
docker compose up --build
```

Access the **Frontend (FE)** by visiting:

 <http://localhost:4748>

Docker Containers

The setup will spawn four containers: - **dp-database** - **dp-server** - **emulate-raspberrypi** - **dp-client**

The provided `docker-compose.yml` file already includes all necessary environment variables for a functional **test environment**. No changes are required to run the project for demonstration purposes.

Default credentials: `admin:test1234`

This account can be used on the frontend to upload and submit WPA handshakes for cracking.

While the software is primarily designed for **Linux**, GPU capabilities can potentially be shared with a containerized `client` via **WSL** on Windows. Future improvements may include native support for additional operating systems.

Project Features

1. Handshake Capturing and Uploading:

Users can capture WPA handshakes using tools like **bettercap** (or similar) and use a **daemon** to upload them to the server. Although referred to as `RaspberryPI` in the project, the daemon can run on any platform supporting **Golang**.

2. Frontend Management:

Users can access the **Frontend (FE)** to:

- View captured handshakes.
- Submit them to clients for cracking.
- Manage connected clients and daemon devices.
- Remove unnecessary handshakes.

3. Independent Clients:

Each **client** operates independently and communicates directly with the server. Users can select which client will handle specific cracking tasks.

4. **Modularity:**

The software is designed with modularity in mind to simplify future changes and improvements.

Architectural Notes

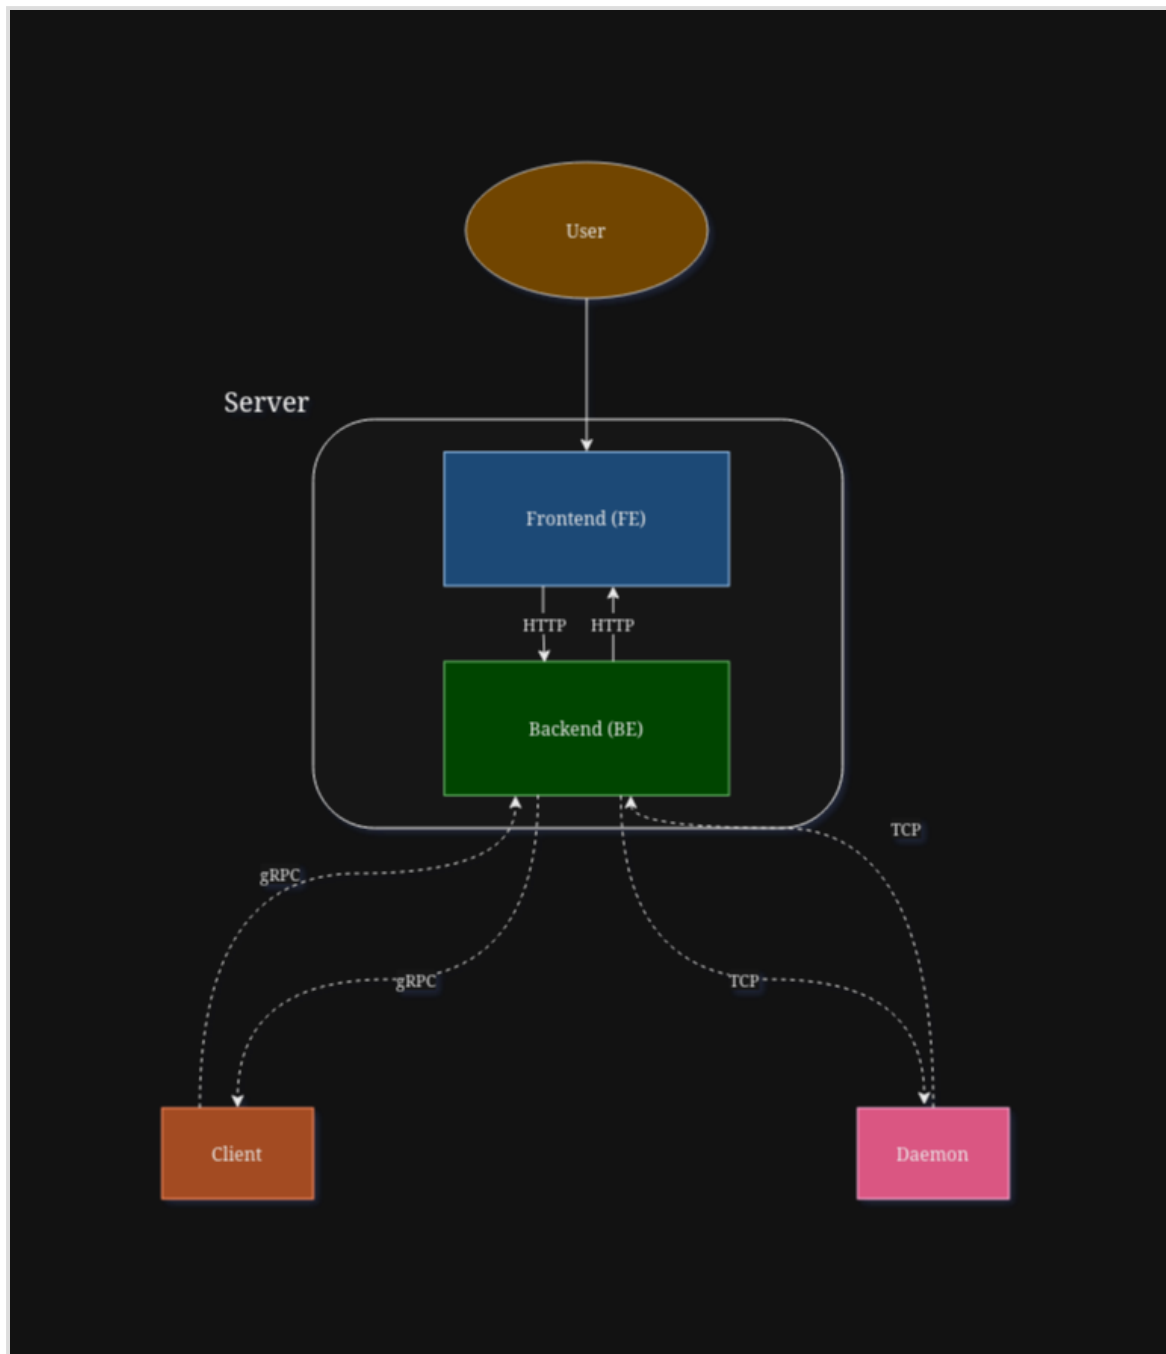

- While a fully **Clean Architecture** approach wasn't strictly followed, both the **Frontend (FE)** and **Backend (BE)** adopt a similar structure.
- **Entities (database models)** reside in the `server` folder and are shared between **FE** and **BE**.
 - If FE and BE are deployed on separate servers, the `entities` directory must be moved into each respective folder. Minor refactoring will be required.
- **gRPC Communication:**

Clients and the backend use **gRPC** for communication. Both must include compiled **protobuf** files:

```
cd client && make proto
```

```
cd server/backend && make proto
```

Project Scheme

As shown in the diagram, the **Backend (BE)** is isolated and can only be accessed through the **Frontend (FE)**.

Communication Flow:

- **FE ↔ BE (HTTP/REST API):**
 - **FE:** Sends HTTP requests to BE.
 - **BE:** Handles database interactions and returns data.

- **Daemon ↔ BE (TCP):**
 - After authenticating via **REST API**, the daemon communicates with BE via raw **TCP**.
- **Client ↔ BE (gRPC):**
 - A **bidirectional gRPC stream** allows clients to dynamically send logs and receive updates during **Hashcat** operations.

Directory Mapping:

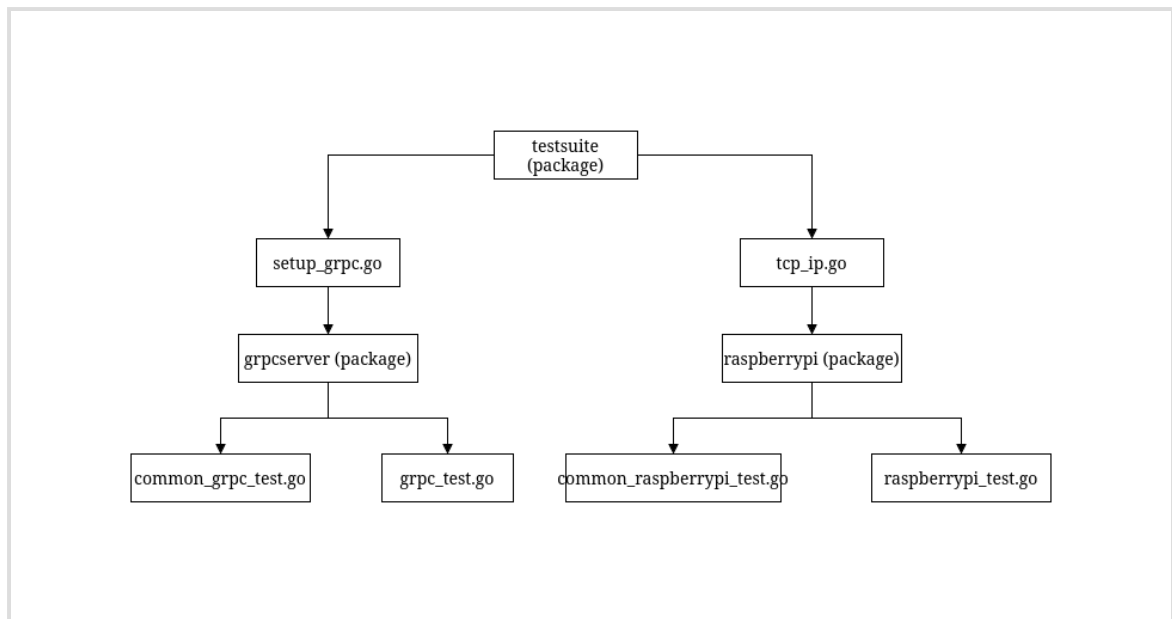

- **Client:** -> /client
 - **Daemon:** -> /raspberry-pi
 - **Server:** -> /server
 - **Backend:** -> /server/backend
 - **Frontend:** -> /server/frontend
-

Test scheme

The tests have been implemented in the backend and emulates `gRPC` and `daemon` clients, for testing out methods of these 2 protocols.

It was not that easy to achieve a good solid test scheme, but at the end it should look like something like this.

When running a test a `gRPC` server or `tcp` server along with rest API is initialized. It depends on what tests you're running. Here will follow a scheme which will explain better the test flows:

- `setup_grpc.go` -> set up a grpc mock server to communicate with. It is initialized during `SetupTest`. Server is killed on `TeardownTest`. A rest API server is initialized too.
- `tcp_ip.go` -> set up a tcp mock server to communicate with. It is initialized during `SetupTest`. Server is killed on `TeardownTest`. A rest API server is initialized too.
- `common_grpc.go` -> calls `SetupTest` and `TeardownTest`, define a structure with mock data useful in tests
- `common_raspberrypi_test.go` -> calls `SetupTest` and `TeardownTest`, define a structure with mock data useful in tests
- `grpc_test.go` -> contains tests for grpc infrastructure
- `raspberrypi_test.go` -> contains tests for raspberrypi infrastructure

A database container must be up and running on port 3306 to succeed.

You can run tests using `cd server && make test` but env variables must be set before proceeding

```
export BACKEND_HOST="0.0.0.0"
export BACKEND_PORT="4747"
export FRONTEND_HOST="0.0.0.0"
export FRONTEND_PORT="4748"
```

```
export DB_USER="agent"
export DB_PASSWORD="SUPERSECUREUNCRAKABLEPASSWORD" # This
               should be changed (remember to change it in
               database/initialize.sql too)
export DB_HOST="localhost"
export DB_PORT="3306"
export DB_NAME="dp_hashcat"
export ALLOW_REGISTRATIONS="True" # Disable if needed
export DEBUG="True" # This will enable seeds for having
               some accounts for testing purposes. admin:test1234
               will be created
export RESET="True"
export GRPC_URL="0.0.0.0:7777"
export GRPC_TIMEOUT="10s"
export TCP_ADDRESS="0.0.0.0"
export TCP_PORT="4749"
```

Security and Future Improvements

While security auditing and privacy were not primary objectives for this project, some measures and considerations have been noted:

1. Encryption:

- Currently, **pcap files** sent by the daemon are **not encrypted**.
- A symmetric encryption key has been generated, but encryption is yet to be implemented.

2. Daemon Authentication:

- Daemon authenticates via **REST API** before establishing a **TCP** connection.
- Credentials are sent via command-line arguments, which could be stolen easily if a malicious actor have access remotely to the machine.

3. Client GUI:

- A GUI exists in the codebase but remains unfinished due to time constraints.
- This feature is not critical to the core functionality and may be revisited later.

4. gRPC Security:

- gRPC communication currently lacks **SSL/TLS certificates** for encryption.

Security Measures Implemented:

- Basic protection against vulnerabilities like **SQL Injection** and **IDORs** has been considered.

If you have suggestions or improvements, feel free to **open a pull request**.

Deamon

The Raspberry Pi component is designed to **send network captures performed by bettercap to the server**. Its functionality is straightforward: you run the `bettercap` daemon on the Raspberry Pi, and it automatically transmits captured handshakes to the server whenever your local Wi-Fi SSID is detected nearby.

This feature is **disabled** if the `TEST` environment variable is set to `False`. Ensure that your Raspberry Pi has at least **two network interfaces**, with one interface always connected to a stable network.

Tested on Raspberry Pi 5 Model B Rev. 2

Update the `wlan1` interface to match your network interface. Make sure your Wi-Fi card supports **monitor mode** and **packet injection**.

What Does the Daemon Do?

The daemon performs the following tasks:

1. Acts as a **TCP/IP client** to establish raw network connections.

2. Scans all `.PCAP` files located in the `~/handshakes` directory (typically where `bettercap` saves handshakes).
 3. Utilizes the `gopacket` library to read `.PCAP` file layers, extracting **BSSID** and **SSID** information, and verifying if a **valid 4-way handshake** exists.
 4. If a valid handshake is detected, the daemon **encodes the file in Base64** and sends it to the server.
 5. Waits for a predefined **delay period** before repeating the process.
-

Run Bettercap

This configuration sets up `bettercap` to capture handshakes and save them in the correct directory.

```
sudo bettercap -iface wlan1 -eval 'set
    wifi.handshakes.aggregate false; set
    wifi.handshakes.file ~/handshakes; wifi.recon on;
    set wifi.show.sort clients desc; set ticker.commands
    "wifi.deauth *; clear; wifi.show"; set ticker.period
    60; ticker on';
```

The daemon uses the `HOME` directory as its base. Since `bettercap` requires `sudo`, you must run the daemon as `root`.

Other Useful Bettercap Commands

These commands can help you fine-tune your `bettercap` setup:

```
sudo bettercap -iface wlan1
wifi.recon BSSID
wifi.recon on
wifi.recon.channel N; # N is the channel to recon
```

Compile and Run the Daemon

Make sure the following requirements are met before building and running the daemon:

The daemon requires `libpcap0.8-dev` to be installed on your system.

The file `/etc/machine-id` must exist on your machine.

Follow these steps to compile and run the daemon:

```
cd raspberry-pi
go mod verify
go mod tidy
go build main.go
sudo ./main
```

Client

Clients communicate with the server using `gRPC`. This enables clients to identify whether they are the intended receiver for a specific cracking task.

The communication channel also supports a **bidirectional stream**, allowing the server and client to exchange messages in real time during `hashcat` execution.

What Does the Client Do?

A client performs the following tasks:

1. **Waits for tasks** from the server.
2. Upon receiving a task, it **acknowledges the server**.
3. The server then **removes the task from the pending queue** and updates its status. Meanwhile, the client saves the **base64-encoded hash file** into a temporary directory.

4. Once saved as a **.PCAP file**, the client converts it into a **hash format compatible with hashcat**.
 5. The client uses **hcxtools** for the conversion. This library supports multiple operations on **.PCAP** files and beyond.
 6. After conversion, **hashcat begins execution**, applying user-defined or default options.
 7. **Logs and status updates** generated by **hashcat** are sent asynchronously to the server.
 8. If **hashcat** successfully cracks the password, the **result is sent back to the server**.
 9. The client then resets itself and **waits for the next task**.
-

Gocat

The client uses the **gocat** dependency to execute **hashcat** from within Go. Since **hashcat** is written in **C**, a **porting layer** was required to bridge the two environments.

Hcxtools

For our use case, we rely specifically on **hcxpcapngtool** from the **hcxtools** suite.

This tool doesn't natively support building as a shared library. To work around this limitation and enable its integration with Go, we **modified its entry point** using **sed**:

```
sed -i 's/int main(int argc, char \*argv\[\\]) /int  
      convert_pcap(int argc, char \*argv\[\\]) /'  
      hcxpcapngtool.c
```

This command replaces the standard **main** function signature with **convert_pcap**. We then compile it into a shared library:

```
cc -fPIC -shared -o /app/client/libhcxpcapngtool.so /app/  
    hcxtools/hcxpcapngtool.c -lz -lssl -lcrypto -  
    DVERSION_TAG=\"6.3.5\" -DVERSION_YEAR=\"2024\"
```

This shared library can now be directly imported and used in Go:

File: client/internal/hcxttools/hcxpcapngtool.go

```
/*
#cgo LDFLAGS: -L../.. -lhcxpcapngtool
#include <stdlib.h>

// Declare the convert_pcap function from the shared library
int convert_pcap(int argc, char *argv[]);
*/
import "C"
import (
    "fmt"
    "unsafe"
)

func ConvertPCAPToHashcatFormat(inputFile, outputFile string)
    error {
    // Prepare arguments for the convert_pcap function
    args := []string{"", inputFile, "-o", outputFile}
    argc := C.int(len(args))
    argv := make([]*C.char, len(args))

    // Convert Go string slices to C strings
    for i, arg := range args {
        argv[i] = C.CString(arg)
        defer C.free(unsafe.Pointer(argv[i]))
    }

    // Call the convert_pcap function from the shared
    library
    ret := C.convert_pcap(argc, &argv[0])
    if ret != 0 {
        return fmt.Errorf("hcxpcapngtool conversion failed
            with code %d", ret)
    }
}
```

```
    return nil
}
```

While this solution works for our current requirements, future improvements could include **porting the library fully to Go**. However, this is considered **out of scope** for the current project.

Compile and Run

The following dependencies are required before proceeding

```
apt update -y && \
  apt install -y --no-install-recommends \
  libminizip-dev \
  ocl-icd-libopencl1 \
  opencl-headers \
  pocl-opencl-icd \
  build-essential \
  wget \
  git \
  dumb-init \
  ca-certificates \
  libz-dev \
  libssl-dev \
  dbus \
  # Graphic libraries for raylib
  libgl1-mesa-dev libxi-dev libxcursor-dev libxrandr-dev
  libxinerama-dev libwayland-dev libxkbcommon-dev
```

The file `/etc/machine-id` must exist on your machine.

Follow these steps to compile and run the client, run it from project root dir

```
git submodule init
git submodule update
git pull --recurse-submodule
```

Then

```
BASE=${PWD}

# Environment Variables
export HASHCAT_SRC_PATH="${BASE}/client/hashcat"
export CGO_CFLAGS="-I$HASHCAT_SRC_PATH/OpenCL -I$HASHCAT_SRC_PATH/deps/LZMA-SDK/C -I$HASHCAT_SRC_PATH/deps/zlib -I$HASHCAT_SRC_PATH/deps/zlib/contrib -I$HASHCAT_SRC_PATH/deps/OpenCL-Headers $CGO_CFLAGS"

Server

The **Server** is divided into two main components:

- **Backend**
 - **Frontend**
-

What Does the Backend Do?

The **backend** performs the following tasks:

1. Initializes a connection with the **database**.
 2. Starts a basic `HTTPServer` to expose the **REST API**, potentially creating **seeds/mock data** for testing purposes.
 3. Initializes a `gRPC` server to handle communication with **clients**.
 4. Initializes a `TCP` server to handle communication with **daemons**.
 5. Encapsulates the **core application logic queue**.
-

What Does the Frontend Do?

The **frontend** performs the following tasks:

1. Starts a basic `HTTPServer` and parses **template files** to expose a user interface.
 2. Accepts **user inputs** and communicates with the **backend** using `REST API` by performing **HTTP requests**.
-

Compile and Run

You need to export the following **environment variables**. Customize them as needed.

1. Start Database

```
cd database
docker build -t dp-database .
docker run -d \
--name dp-database \
-e MYSQL_RANDOM_ROOT_PASSWORD=yes \
--restart unless-stopped \
-p 3306:3306 \
--health-cmd="mysqladmin ping -h localhost -uagent -
```

```
pSUPERSECUREUNCRACKABLEPASSWORD" \  
--health-interval=20s \  
--health-retries=10 \  
dp-database
```

2. Export Environment Variables

```
export BACKEND_HOST="0.0.0.0"  
export BACKEND_PORT="4747"  
export FRONTEND_HOST="0.0.0.0"  
export FRONTEND_PORT="4748"  
export DB_USER="agent"  
export DB_PASSWORD="SUPERSECUREUNCRACKABLEPASSWORD" # This  
should be changed (remember to change it in database/  
initialize.sql too)  
export DB_HOST="localhost"  
export DB_PORT="3306"  
export DB_NAME="dp_hashcat"  
export ALLOW_REGISTRATIONS="True" # Disable if needed  
export DEBUG="True" # This will enable seeds for having  
some accounts for testing purposes. admin:test1234 will be  
created  
export RESET="True"  
export GRPC_URL="0.0.0.0:7777"  
export GRPC_TIMEOUT="10s"  
export TCP_ADDRESS="0.0.0.0"  
export TCP_PORT="4749"
```

3. Compile and Run the Server

```
cd server  
make proto  
go mod tidy  
go build main.go  
./main
```

After completing these steps, the **server** should be up and running, with both the **frontend** and **backend** components functioning as expected.

External Dependencies

Ignoring gRPC and other basic deps

- **RayLib** github.com/gen2brain/raylib-go/raylib A basic graphic library
- **Gocat** github.com/mandiant/gocat/v6 Used for running hashcat in go via `hashcatlib`
- **Validator** github.com/go-playground/validator/v10 Validator for go structures
- **Mux** github.com/gorilla/mux HTTP router
- **Testify** github.com/stretchr/testify A test library for simplifying test syntax
- **Gopacket** github.com/google/gopacket Parse `.PCAP` files as layers
- **Wifi** github.com/mdlayher/wifi used by daemon for understanding if we're connected to our local network
- **Cobra** github.com/spf13/cobra used for parsing command line arguments easily in daemon
